## IARC Conclusions

There is sufficient evidence in humans for the carcinogenicity of all forms of asbestos (chrysotile, crocidolite, amosite, tremolite, actinolite, and anthophyllite).

They causes mesothelioma, cancer of larynx, lung and ovary. All forms of asbestos are carcinogenic to humans (Group 1).

# Lung cancer risk in exposed to asbestos

- Selikoff, et al. JAMA 1968
- Balmes JR. AJRCCM 2013
- IARC. Mon 100 C. 2012
- Lenters V, et al. EHP 2011
- Markowitz SB, et al. AJRCCM 2013

- Risk increases with cumulative exposure. *Elliott L, et al. Occup Environ Med 2012*
- There is insufficient evidence of potency differences between chrysotile and amphiboles. *IARC; Balmes*
- Fibers of all sizes are associated with risk; risk is greater for longer and thinner fibers. *Loomis D, et al. OEM 2012*
- There is no safe exposure limit. *Deng Q, et al. OEM 2012*
- Asbestosis increases risk
- Smoking increases and cessation decreases risk

# Risk of lung cancer deaths and cumulative exposure to chrysotile - cohort 577 exposed, followed by 37 years (China)

Courtice MN, et al. AJIM 2016

# Mortality in workers exposed to chrysotile- North Carolina / USA

Loomis D, e col. OEM 2009

- Cohort study with 5,770 workers (between 1950 and 1973)
- **Results**

	SMRs	(CI95%)
– Lung cancer	1.96	(1.7 – 2.2)
– Mesotheliome	10.9	(3.0 – 28.0)
– Pleural cancer	12.4	(3.4 – 31.8)
– Asbestosis	3.5	(2.7 – 4.4)
- Standardised mortality ratios (SMRs) increased with cumulative exposure

# Exposure to different fibers and lung cancer

McCormack V, e col. BrJ Cancer 2012

- Data analysis of 55 cohort studies
- Risk of lung cancer mortality
- **Results:**
  - For all fibers, the risk of death from Ca Lung was double

Tipo de asbesto	Razão de Mortalidade por CP padronizada
<b>Crocidolite (6)</b>	2.0 (1.6 – 2.7)
<b>Chrysotile (16)</b>	1.7 (1.4 - 2.0)
<b>Amosite (4)</b>	2.5 (1.4 - 4.3)

# Cohort of the exposed to chrysotile (China)

Wang X, et al. Thorax 2012

## Prospective cohort from 1972 to 2008 (37 years)

	Deaths	LC deaths	Resp diseases
• 577 exposed	259 (45%)	53	81
• 435 controls	76 (18%)	9	11

## Exposed to asbestos x non exposed (Relative risk; CI 95%)

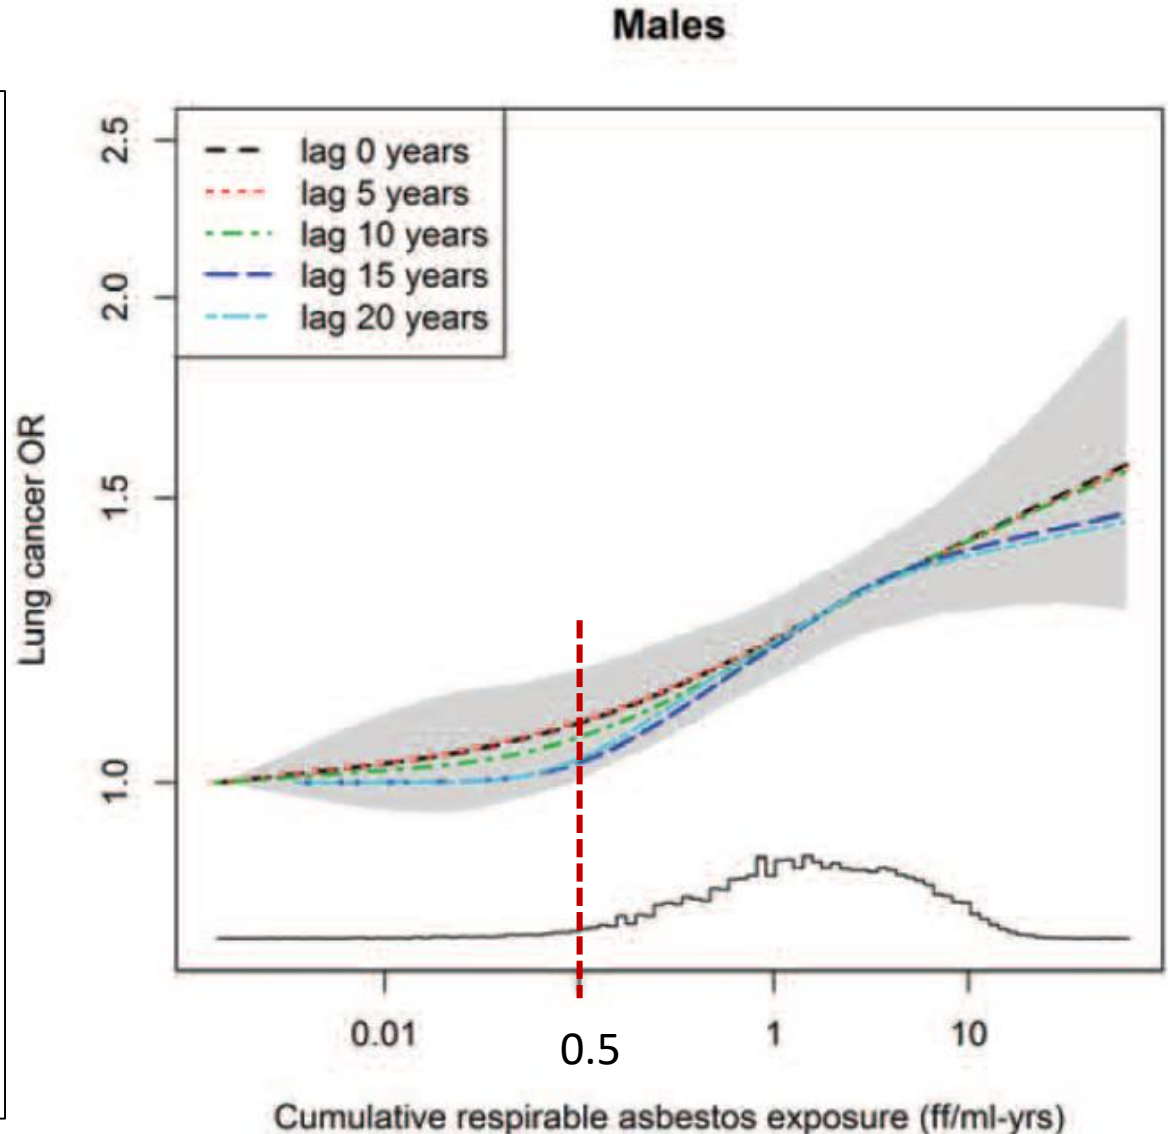

• Lung cancer deaths	3.3	(1.6 - 6.9)
• Respiratory diseases deaths NM*:	3.2	(1.7 - 6.2)

\***NM: non malignants**

# Lung cancer: Exposure-response to low cumulative exposure to asbestos

Olsson AC, et al. *Epidemiology* 2017

Pooled Analysis of 14 Case-Control Studies (cases:7,700; control: 21,800, on European countries and Canada (1985-2010). Figure - data adjusted for smoking, age. Median of cumulative exposure - 1.21 ff-year/ml and 0.57 ff -year/ml, for men and women, respectively.

# Exposure to chrysotile, smoking and lung cancer deaths (cohort in China) - dose-response

Wang X, e col. Thorax 2012

	Non -smokers RR (IC 95%)	Smokers RR (IC 95%)
<b>Control cohort</b>	1.00	6.03 (0.75 - 48.21)
<b>Asbestos cohort</b>	7.5 (0.9 - 62.8)	17.4 (2.4 - 126.6)
<b>Exposure level</b>		
<b>Low</b>	2.1 (0.13 - 33.2)	10.7 (1.4 - 81.6)
<b>Medium</b>	6.4 (0.4 - 102.7)	18.4 (2.3 - 145.9)
<b>High</b>	26.2 (2.9 - 234.9)	28.6 (3.8 - 213.6)

# Lung cancer - USA cohort: 1981- 2008.

## Impact of exposure to asbestos and tobacco

Markowitz SB, et al. AJRCCM 2013

- 2,377 asbestos exposed x 54,243 unexposed
- Lung cancer death risks

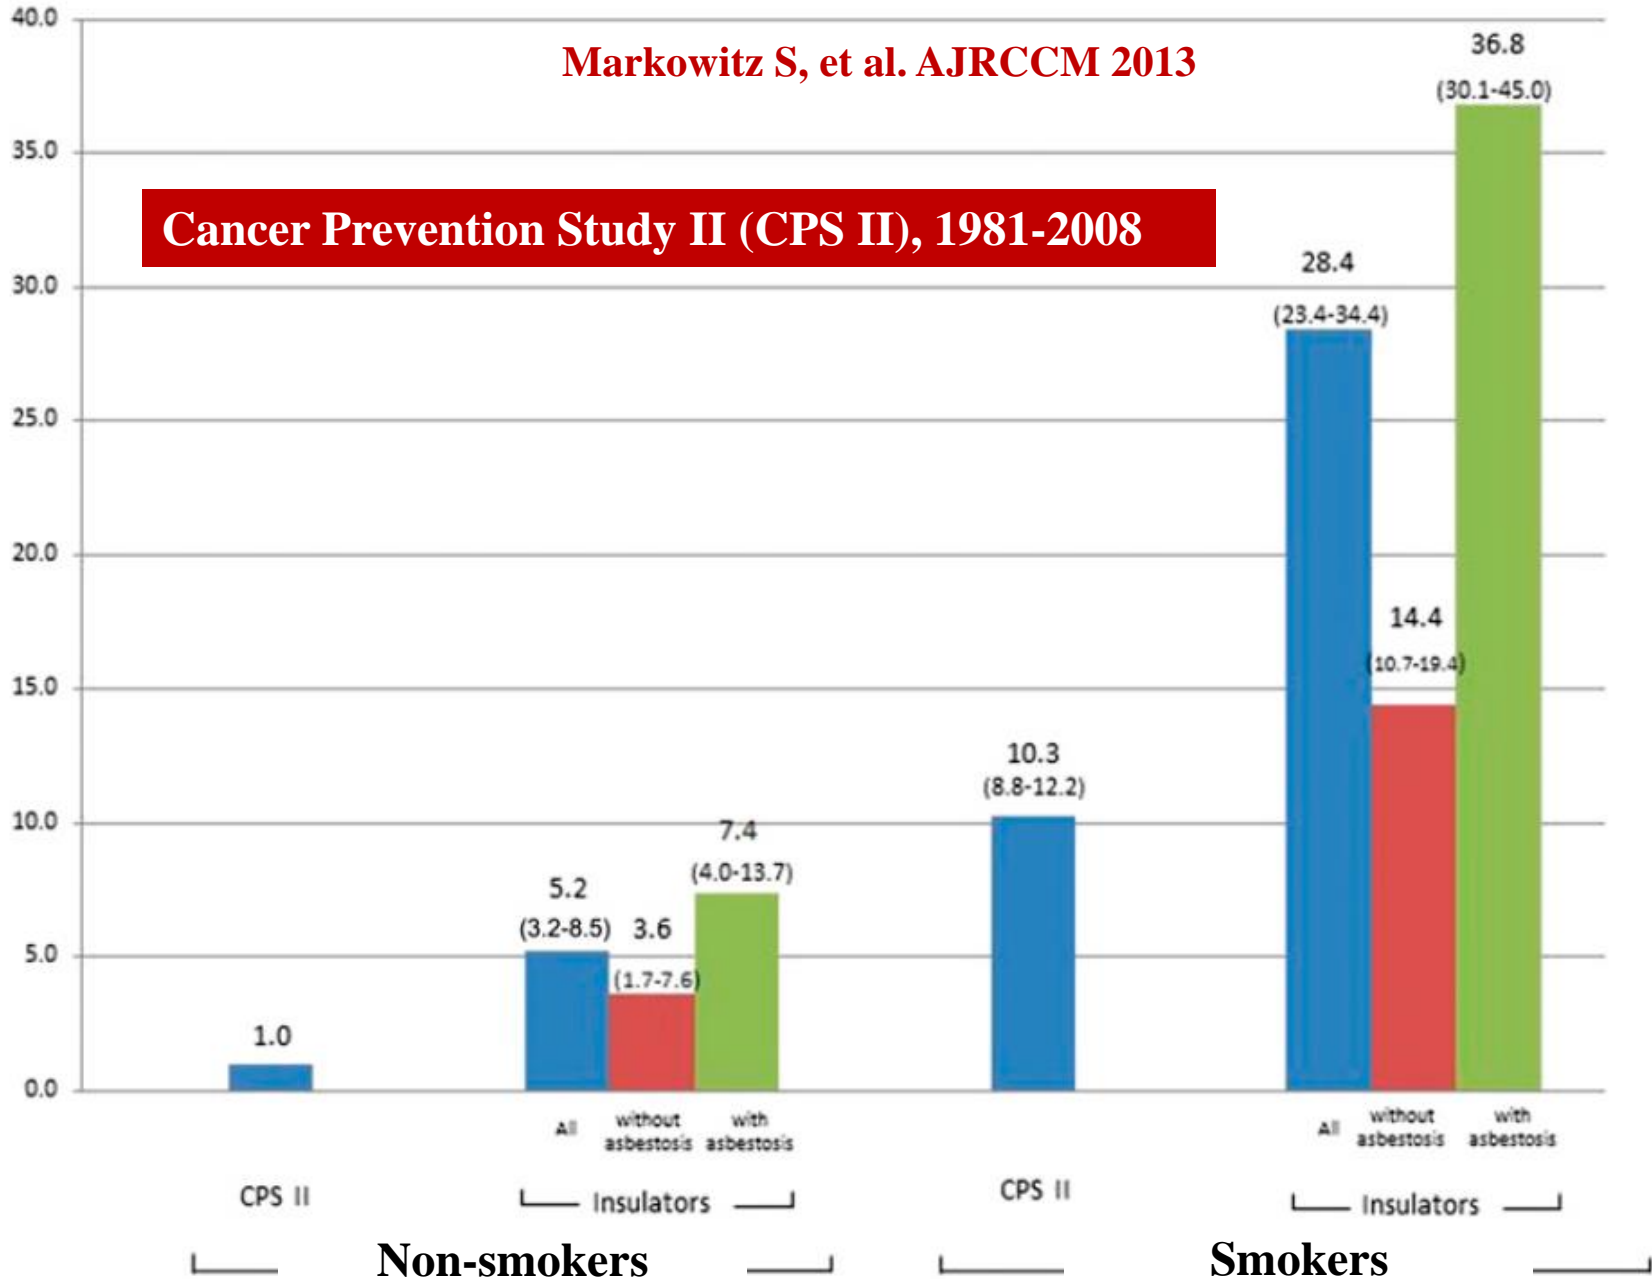

• Exposed no asbestosis and N-Smokers:	3.6 (IC95%: 1.7-7.6)
• Asbestosis and N-Smokers:	7.4 (IC95%: 4.0-13.7)
• Smokers, not exposed to asbestos:	10.3 (IC95%: 8.8-12.2)
• Smokers, exposed, no asbestosis:	14.4 (IC95%: 10.7-19.4)
• Smokers with asbestosis:	36.8 (IC95%: 30.1-45.0)

# Asbestos, asbestosis, smoking and Lung cancer deaths

Sayan & Mossman. Particle and Fibers Toxicology 2016

Macrophage, epithelial cells, monocytes

# Criteria for assigning lung cancer to asbestos

- Diagnosis of lung cancer
- History of occupational, environmental, or domestic exposure and / or
- Information on the working or living environment
  - Exposure time
  - Cumulative exposure quantitative/qualitative- exposure load
- Latency
- Asbestos exposure markers

# Lung cancer - approach for diagnosis

- Image exams
- biopsy of lymphnodes: supraclavicular, cervical, axillary
- Bronchoscopy with BAL and endo and / or transbronchial biopsy or by EUS/EBUS
- Medistinoscopy
- Transthoracic biopsy guided by CT
- Biopsy open/video
- Histological examination
- Immunohistochemistry

# Lung Cancer and Asbestos: Attribution Criteria-1

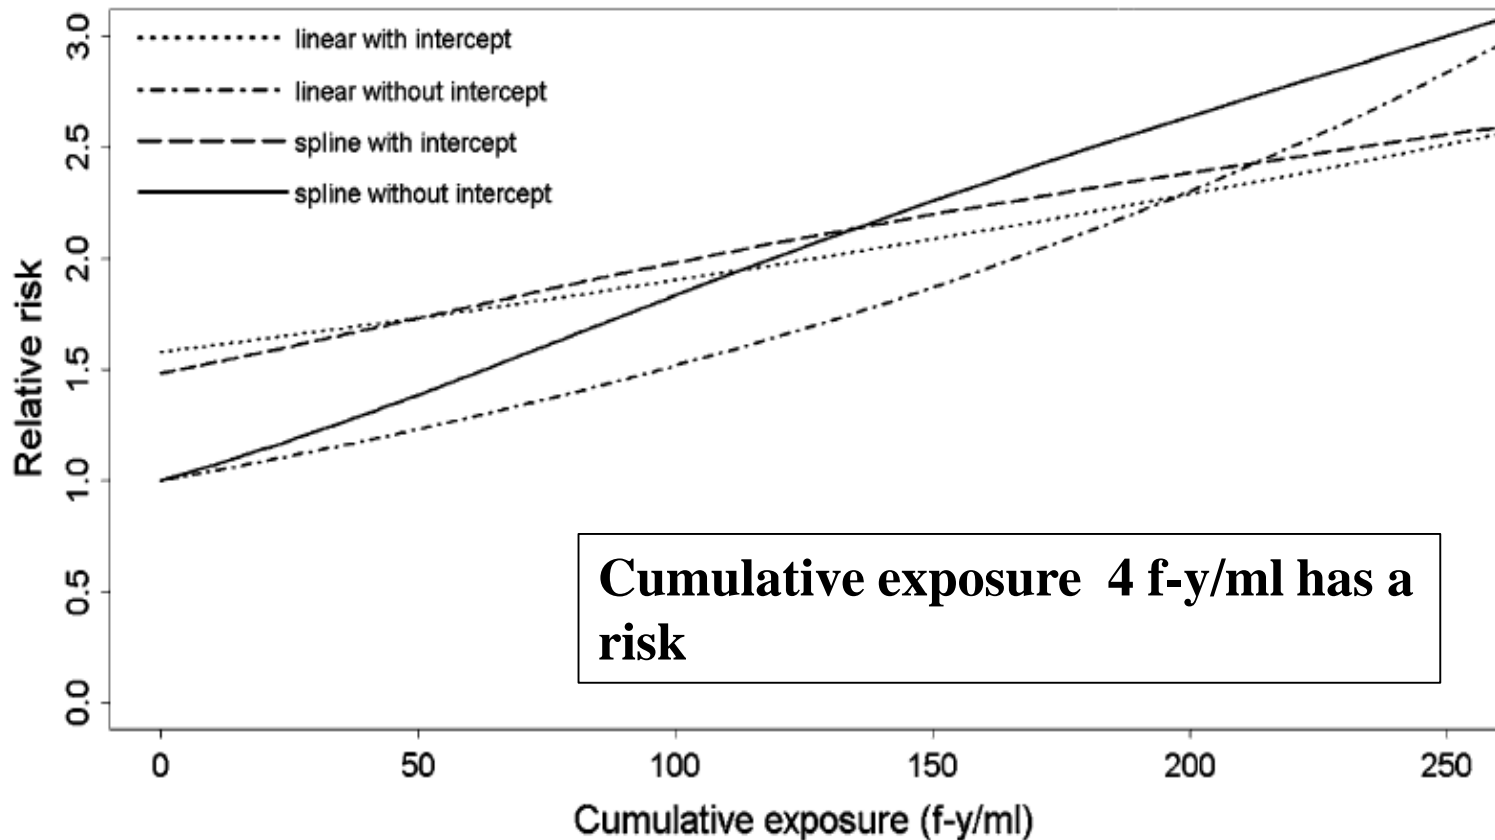

- **Wolff H, et al Helsinki Criteria 2014. Scand J Work Environ Health 2015**
- **IARC Mon 100 C 2012**

- All types: squamous, adenocarcinoma, small and large cells, sarcomatoid and adenosquamous carcinoma
- Histological type and location has no value for assignment
- Risk increases with exposure - dose response
- Cumulative exposure - main criterion for attribution
  - Risk increases from 0.5% to 4%/fiber/cm<sup>3</sup>/year (fiber years) of cumulative exposure
  - 25-year fiber exposure - risk increases twice, even without detectable asbestosis
  - Exposure <25 years-fiber, also increases risk, but is lower

# Exposure

IARC. Mon 100 C. 2012; Van der Bij S, et al. Cancer Causes Control 2013<sup>2</sup>

- Occupational - proven evidence<sup>1</sup>
- Environmental- more controversial studies, but.<sup>1,2</sup>

# Attribution Criteria-2

- Helsinki Criteria 1997/2014
- IARC mono 100C, 2012
- Occupational history (fibers-years exposure) - best indicator for chrysotile
- Latency > 10 years
- 1 year or - of intense exposure = 5-10 years of moderate and increases the risk of lung cancer in 2 times
- Diffuse, bilateral pleural thickening → moderate / severe exposure is attribution criterion
- Pleural plaque is an exposure indicator
  - Mas individualmente não é suficiente para atribuição
- Asbestosis is not necessary, but contributes with additional risk

# High probability of asbestos exposure

Helsinki Criteria 1997/2014

## Complementary data to occupational history

- Over 0.1 million amphibole fibers ( $>5 \mu\text{m}$ )/g of dry lung tissue, or
- Over  $10^6$  amphibole fibers ( $>1 \mu\text{m}$ )/g of dry lung tissue measured by EM, or
- Over 1000 asbestos bodies/g of dry lung tissue (100 asbestos bodies/g wet lung tissue), or
- Over 1 asbestos bodies/ ml de bronchoalveolar lavage fluid (BAL)
- Each laboratory should establish its own reference values

# Asbestosis with diffuse thickening and pleural plaques

# OMS, woman, 71 years old - soapstone handicraft

**Woman, 65 years old, polishing/scraping of asbestos tiles, in the house, for over 20 years, latency 42 years**

Worked at  
Brasilit from  
1966-68

**71 years old, worked 8 months manufacturing joints with asbestos. Latency 50 years**

**WS, 70 years old, smoker. He reported pain in HTD radiating to MSD. Worked at Cia. Metalúrgica Barbará (Saint-Gobain group).**

**EVS - worked at Eternit from 1966 to 1980**

**JAF, 78 years old: Chronic cough and weight loss.  
Former smoker. Worked at Eternit from 1963 to 1985**

## Adenocarcinoma

- Asbestos bodies in LBA
- Pleural plaques
- Latency: 49 years
- Without asbestosis

# Worker - JAD

- Worked at Eternit from 1976 to 1991
- In 2001 (63 years old) : pulmonary nodule on chest CT
  - Adenocarcinoma
- Pneumonectomy due to pulmonary nodule in 2002
- Former smoker, he ceased at 37 years old
- Latency 25 years
- Without asbestosis and/or pleural alterations
- 2013: new pulmonary nodule

# Worker JAD in 2016

# Attribution Criteria-3

**Helsinki Criteria 1997/2014**

- Not all criteria need to be present for attribution, ex:
  - Significant exposure to chrysotile, low number of fibers, but long latency between end of exposure
- Presence of asbestos bodies or a high fiber count in the lung or BAL, with a history of uncertain or short-term exposure
  - should be considered for attribution
- Smoking does not decharacterizes asbestos cancer attribution

# Some comments about the Helsinki Criteria

- Landrighan PL. *Annals of Global Health* 2016
- Collegium Ramazzini. *SJWEH/Industrial Health* 2016

1. Excessive confidence in the detection of "asbestos bodies" and in the count of fibers in the lung, as indicators of past exposure to asbestos.
2. Use of scanning electron microscope (SEM) with low magnification, as a tool for assessing asbestos-related diseases.
3. Failure to recognize that chrysotile is the predominant type of asbestos fiber found in pleural mesothelioma tissue.
4. Postulate the existence of a threshold for the development of lung cancer related to asbestos
5. Change in classification to consider asbestosis

## **CONCLUSIONS:**

- The diagnosis should be based on a occupational history carefully obtained. A precise exposure history is a much more sensitive and specific indicator of asbestos exposure, than asbestos body count or lung fiber burden analysis
- Recommends review of pathology criteria proposed in the diagnostic by Helsinki criteria 2014

# Structural alteration - Histology

Craighead JE. Arch Pathol Lab Med 1982

Green FHY, Attifield M. Scand J Work Environ Health 1983

- Open biopsy - only dubious situations
- Structural change
  - **Grade 0: No fibrosis associated with bronchioles**
  - Grade 1: Fibrosis involving the wall of at least one respiratory bronchiole with or without extension into the septa of the adjacent layer of alveoli
  - Grade 2: Grade 1 + involves alveolar ducts and / or two or more layers of adjacent alveoli
  - Grade 3: whole acinar structure is involved, between two or more respiratory bronchioles have thickened, fibrotic septa; some alveoli may be obliterated completely
  - Grade 4: honeycombing

# Structural alteration - Histology

Rogli VL, et al. Arch Pathol Lab Med 2010

**Table 3. Histologic Grading<sup>a</sup> Scheme for Asbestosis**

Grade	Description
Grade 0	No appreciable peribronchiolar fibrosis, or fibrosis confined to the bronchiolar walls
Grade 1 <sup>b</sup>	Fibrosis confined to the walls of respiratory bronchioles and the first tier of adjacent alveoli
Grade 2 <sup>b</sup>	Extension of fibrosis to involve alveolar ducts and/or $\geq 2$ tiers of alveoli adjacent to the respiratory bronchiole, with sparing of at least some alveoli between adjacent bronchioles
Grade 3	Fibrotic thickening of the walls of all alveoli between $\geq 2$ adjacent respiratory bronchioles
Grade 4	Honeycomb changes

# More Comments

- Companies or the State have not and / or do not provide records of exposure levels throughout their working life
- They claim that workers may not be able to accurately recall asbestos exposures. And tend to overestimate to get insurance. **Gibbs A et al. Arch Pathol Lab Med 2007**
- So, the only valid criterion would be asbestosis. **Gibbs A et al. Arch Pathol Lab Med 2007**
- Or, in the doubt about the exposure, to make count of fibers in the tissue - necessity of biopsy (iatrogeny) - **Helsinki 2014**
- For chrysotile it is better the exposure in fiber-year, than tissue analysis- **Helsinki 2014**
  - *Who measures and supplies data to workers?*
- Occupational history is the gold standard. **Bégin R &Christiman JW. AJRCCM 2001; Landrighan/2016; C Ramazzini/2016; Sartorelli E, 1980**

# Conclusions

- Occupational history and/or environmental data on exposure should be the main attribution factor
- Exposure time and latency should be considered
- Exposure markers - plaques, diffuse thickening, asbestos bodies in the BAL
- If responsables for exposure (companies) and surveillance (State) do not have information on exposure, validated
  - It does not make sense the worker to demonstrate, through submission to a surgical procedure, that has been exposed enough
